**Abstract**

Erectile dysfunction (ED) due to diabetes mellitus remains difficult to treat despite advances in pharmacotherapeutic approaches in the field. Therefore, this study investigated the erectogenic effect of the methanolic extract of *Maytenus procumbens* on type 2 diabetes in rats. The fructose-streptozotocin model was used to induce type 2 diabetes-linked ED in male rats. The sexually active rats were randomly divided into two major groups; normal group and high fructose fed group for 120 days. After 120 days, the high fructose fed group rats were given a single intraperitoneal injection of a freshly prepared streptozotocin solution (30 mg/kg). The diabetic ED rats were orally administered with the extract at 250 mg/kg, daily for 28 days. The serum, brain and penile tissues were removed for biochemical analysis and protein expression. Increased testosterone level, mounting frequency, reduced blood glucose level and serum fructosamine content were observed after 28 days of treatment in diabetic rats. Methanolic extract also exhibited an inhibitory effect on arginase, AChE and ACE activities. The crude extract further downregulated proteins PDE-5, RhoA and increased expression of eNOS in the diabetic ED treated rats. The results obtained indicate that the methanolic extract of *Maytenus procumbens* roots ameliorates erectile dysfunction in type 2 diabetic induced erectile dysfunction in rats.

**Keywords:** Erectile dysfunction; Phosphodiesterase-5; cyclic guanosine monophosphate; *Maytenus procumbens*

**Introduction**

Erectile dysfunction (ED), the most common form of sexual dysfunction in sexually active men, is defined as the repeated inability to attain and maintain an adequate erection for satisfactory sexual intercourse. ED results from the loss of penile vascular and smooth muscle relaxation due to multiple pathophysiological conditions such as hypogonadism, hypertension, type 2 diabetes mellitus (T2D), etc. [1]. Approximately, 90% of T2D men worldwide have been reported to have ED [2]. However, studies have shown that most clinicians do not enquire about sexual dysfunction during medical consultations and the prevalence of self-reported ED is also very low [3, 4].

The pathogenesis through which T2D induces ED result from multiple factors, such as increased formation of advanced glycation end products (AGEs), oxidative stress, deficiency in the nitric oxide-cyclic guanosine monophosphate (NO-cGMP) signaling pathway and hypogonadism [5, 6]. Among these factors, increased formation of AGEs is well-known to form covalent bonds with vascular collagen, causing a vascular thickening, reduced elasticity, endothelial dysfunction, increased vascular stiffness
and subsequently results to ED [7]. Biomolecules such as testosterone, cGMP, NO, and acetylcholine (ACh) play a crucial role in penile erection processes [8]. For instance, the continuous decreased activity of nitric oxide synthase (NOS) which lead to a decreased NO production and depleted cGMP in the penile tissue and thus stimulate ED. Furthermore, literature also suggests that increased activities of acetylcholinesterase (AChE), arginase and angiotensin converting enzyme (ACE) are some causative agents of ED [9, 10]. Studies have shown that insulin enhance the expression of endothelial nitric oxide synthase (eNOS) and subsequently stimulate NO production [11, 12]. These actions of insulin are inhibited by the upregulation of RhoA, a small GTase which stimulates Rho-kinase II (ROCK II) activity and directly inhibits expression of eNOS [13].

Furthermore, literature also suggests that increased activities of acetylcholinesterase (AChE), arginase and angiotensin converting enzyme (ACE) are some other contributing factors to the development of ED [10, 11].

Hence, in an attempt to ameliorate this medical condition (ED), there is currently a rapid increase in the number of men’s clinic. ED is currently treated with Sildenafil (Viagra) and Tadalafil (Cialis), which are all well known as PDE-5 inhibitors. However, these drugs are associated with adverse effects, and a large number of T2D men suffering from ED are refractory to these ED therapies [14]. Thus, the other approaches with less adverse effects could be employed in the discovery of new ED therapies, despite the broad research on ED therapy for many decades.

The use of medicinal plant extracts, due to their multi-target nature, continue to attract attention of researchers in a bid to discover new drug regime against various ailments, including ED. Maytenus procumbens (Celastraceae), which is predominantly in KwaZulu Natal, South Africa, is commonly used by Zulu traditional healers to treat several diseases, linked to sexual dysfunction in men [15, 16]. The ameliorative effect of methanol roots extract of M. procumbens on butanol induced testicular dysfunction in Sprague Dawley rats has been reported [17]. The ameliorative effect was associated with the regeneration of spermatogonia in the seminiferous tubules, increased serum testosterone, sperm count and mount frequency of the rats. However, the molecular mechanism associated with this ameliorated sexual performance remains to be elucidated. Thus, this study investigated the methanolic extract of M. procumbens roots in type 2 diabetic induced erectile dysfunction in Sprague Dawley rats.

Materials and Methods

Chemicals and reagents

All chemicals and reagents used in this study were of analytical quality and all were purchased from Sigma-Aldrich Chemical Co., St. Louis, MO, USA.

Extract preparation

Maytenus procumbens roots were collected from Ndumo and confirmed by a qualified botanist at the Botany Department, University of Zululand, KwaZulu Natal, South Africa. The roots were thoroughly washed, chopped, air dried and ground into powder. The powdered plant material was extracted (1:5 w/v) with methanol to obtain methanolic crude extract. Thereafter, the methanolic extract was filtered through Whatman No. 1 filter paper. The methanol extract was then concentrated under reduced pressure at 40 °C using a rotary evaporator (Heidolph). The crude extract was then ready to be used for the biological assays.

Animals

Ethical clearance (UZREC 171110-030 PGD 2018/230) for approval of procedures and use of laboratory animals was obtained from the University of Zululand Research Ethics Committee (UZREC). Sprague-Dawley rats (06 – 12 weeks of age) were obtained from the laboratory animal unit of Biochemistry and Microbiology Department, University of Zululand. Rats were kept under standard laboratory conditions (at 23 ± 2 °C, 60% humidity and day-night cycle under light) as outlined in the institutional and national guidelines for handling and caring of science laboratory animals. The rats were allowed to acclimatize for at least five days with free access to enough normal rat feed and drinking water before the experiment commenced.

Induction of type 2 diabetes

Type 2 diabetes was induced using the method previously described by Pereira [18] with some modifications. Briefly, Sprague Dawley rats were randomly divided into two major groups; normal group (normal diet and drinking tap water) and high fructose fed group (normal diet and 25% of fructose in drinking water). The animals were put of high fructose for a period of 120 days. After 120 days, the high fructose fed group rats were fasted overnight and they were then given an intraperitoneal injection of a low single dose (30 mg/kg) of a freshly prepared streptozotocin (STZ) solution. After five days of the STZ injection, blood glucose levels were measured with a glucometer (Accutrend glucometer; Roche Diagnostics, Mannheim, Germany) from the blood collected from the tail tip. Animals with blood glucose levels equal to or above 09 mmol/l were considered diabetic and used in the study.

Investigation of the erectogenic effect of the plant extract

At the end of the induction of T2D, estrous was induced in a group of female rats (150 – 200 g). These female rats received three consecutive subcutaneous injections of progesterone (7.5 mg/kg, at 24-hour intervals) 96 hours before being introduced to male rats for determination of baseline
sexual behavior of the male rats. After that, the normal group was subdivided into two groups while the diabetic group was also subdivided into four groups of five rats per group as shown in Figure 1.

Thereafter, the experimental groups were orally administered daily with the extract at 250 mg/kg b.w for 28 days. Normal control and negative control (Diabetic ED control) received a carrier solvent while positive controls received an indoor control RA-3 (100 mg/kg b.w) and Cialis (5 mg/kg b.w), respectively. Thereafter, estrous induced group of female rats (induced as described above), were then introduced to male rats for sexual animal behavior, each male rat from various treatment groups was individually subjected to the estrous female rats (n=3) in a separate cage for 30 minutes and the number of mounts was recorded.

Biochemical analysis

At the end of the experimental period, all the male rats were fasted for 8 hours and euthanized under anesthesia. The loss of sensation was confirmed by the pedal withdrawal reflex and assessed by pinching of the tails, prior to blood collection. Blood was immediately collected by cardiac puncture and the penile tissues as well as brains were removed for analysis of significant biochemical assay. The collected blood was allowed to clot and centrifuged for 10 minutes at 3,500 rpm at 4 °C, and serum was collected. The brains were weighed and homogenized in 0.1 M phosphate buffer saline (pH 8.0). The serum levels of some antioxidants (SOD, CAT), MDA content, arginase and ACE activities as well as AChE activity from brain supernatant were estimated using respective commercial activity assay kits (Sigma-Aldrich), suitable for rat samples, following manufacturers’ instructions. The serum testosterone, and uric acid levels were determined using standard laboratory procedures (Global Laboratory & Viral Laboratory, Richards Bay).

Estimation of serum fructosamine concentration

Fructosamine concentration was determined in the serum of the rats using nitro-blue tetrazolium (NBT) assay as previously described by Adisakwattana [19]. Briefly, 125 µl of serum samples from the different groups was incubated with 125 µl of 0.5 mM NBT in 0.1 M sodium carbonate buffer (pH 10.4) at 37 °C for 15 minutes. The absorbance was measured at the wavelength of 590 nm. The concentration of fructosamine (mg/ml) in the respective samples was determined from the standard curve of 1-deoxy-1-morpholino-fructose (1-DMF).

Determination of protein thiol group

The Ellman’s assay was used to also determine the level of protein thiol groups [19]. The serum samples (125 µl) from different groups were incubated with 125 µl of 5 mM 5,5’-Dithiobis (2-nitrobenzoic acid, DTNB) solution for 15 minutes at 37 °C, followed by measuring the absorbance at the wavelength of 410 nm. The free thiol concentration of samples was calculated based on the standard curve prepared by using various concentration of L-cysteine.

Western blot analysis

Western blot analysis of some proteins involved in the erection process were performed. Snap frozen penile muscle tissue (100 mg) was defrosted on ice and lysed in lysis buffer (Pierce Biotechnologies, Rockford, CA, USA) using a Tissue lyser. Thereafter, the samples were centrifuged for 15 minutes at 13,000 rpm at 4 °C. Supernatant was collected and stored at -20 °C until required for use. Protein sample was mixed with an equal volume of 2x Laemmli sample buffer before it was denatured at 95 °C for 5 minutes. The denatured protein samples (30 µg) were loaded on the 12 % SDS-polyacrylamide gel (Bio-Rad, Hercules, CA, USA) and run for 1 hour at 150 V in Tris/Glycine/SDS-PAGE Buffer 1X. The proteins from the gel were then transferred to the polyvinylidene fluoride membrane (PVDF) (Bio-Rad, Hercules, CA, USA) (Johnson et al., 2017). The membranes (containing the proteins) were incubated at 4 °C for 16 hours with the following primary antibodies: anti- PDE-5 (1:500), RhoA (1:500) and eNOS (1:10000) (Sigma-Aldrich Chemical Co., St. Louis, MO, USA). The membranes were washed and incubated with the appropriate horseradish peroxidase conjugated secondary antibody at room temperature for 90 minutes. All proteins

![Figure 1](https://example.com/image.png) Schematic representation of the erectogenic effect of the methanolic roots extract on type 2 diabetic rats.
were normalized to a loading control (β-Actin) (1:500) (Santa Cruz Biotechnology, Dallas, TX, USA). Chemidoc-XRS imager and image lab version 06 software (Bio-Rad Laboratories, Hercules, CA, USA) was used to Detect and quantify the proteins.

**Statistical analysis**

Results are presented as the mean ± standard error of the mean (mean ± SEM) in triplicates. Statistical analysis of the differences between mean values obtained from experimental groups were calculated using GraphPad prism (v6.01). Data were subjected to one-way analysis of variance (ANOVA) followed by Dunnett’s multiple comparison test. \( p \leq 0.05 \) was regarded as statistically significant.

**Results**

**Fasting blood glucose (FBG), Mounting frequency and serum testosterone levels**

Fasting blood glucose levels, mounting frequency and serum testosterone levels in diabetic induced ED rats after 28 days of treatment are shown in Table 1. The untreated diabetic ED rats presented with persistently higher fasting blood glucose levels. However, a slight decrease in the fasting blood glucose level, when compared to untreated diabetic ED group, was observed in diabetic ED rats treated with the extract for 28 days. Relatively lower testosterone levels, and mounting frequency when compared to the normal group, were also observed in untreated diabetic ED group. However, an increase \( (p<0.001) \) in the tested parameters was evident in the animals treated with the extract.

**Serum fructosamine, protein thiol group content and uric acid**

Figure 2 shows the results of the effect of the extract on serum fructosamine, protein thiol group content and uric acid of the diabetic induced ED rats after 28 days of treatment. Elevated serum levels of fructosamine and lower protein thiol group were observed in the untreated diabetic animals or diabetic animals treated with Cialis, respectively, when compared to the normal control group. However, lower serum levels of the fructosamine content accompanied by a significant increase in protein thiol group concentrations were observed in the diabetic rats treated with the extract or RA-3 when compared to the untreated diabetic animals (Figure 2). Furthermore, a decreased uric acid level was also observed in the diabetic ED group treated with the extract or RA-3 when compared with an increase uric acid level in the untreated diabetic ED group.

Effect of the extract on serum antioxidant status

Table 2 shows the results of the effect of the extract on some serum antioxidant levels in the diabetic induced ED rats. Significantly lower SOD and CAT levels along with a relatively higher MDA level were observed in the untreated diabetic ED group animals when compared to the normal control group. However, treatment of the diabetic rats with either extract or RA-3 displayed a significantly ($p \leq 0.001$) increased SOD and CAT levels in comparison to the untreated diabetic-ED animals. This was accompanied by a significant ($p \leq 0.01$) decrease in the MDA levels in extract or RA-3 treated groups.

Effect of the extract on the serum levels of ACE, AChE and arginase

The results of the effect of methanolic roots extract on ACE, AChE and arginase activities are presented in Figure 3. A significantly ($p \leq 0.001$) higher enzyme activities were observed in the untreated diabetic ED rats when compared with the normal control group. However, administration of the extract to the diabetic ED rats for 28 days, significantly ($p \leq 0.001$ and $p \leq 0.0001$) decreased the enzyme activities when compared to the untreated diabetic ED group.

Effect of the extract on the expression of PDE-5, RhoA and eNOS

Effect of the plant extract on the expression of some proteins involved in penile erection process was also investigated. The upregulation of PDE-5 (Figure 4A) and RhoA (Figure 4C) accompanied by down regulated eNOS (Figure 4B) were observed in untreated diabetic ED group when compared to normal rats. A significantly lower expression of PDE-5 and RhoA along with an increased expression of eNOS were observed in the penile tissues of the diabetic induced ED group.

treated with the extract. Furthermore, a significant decreased expression of PDE-5 and RhoA in the diabetic ED groups treated with RA-3 and Cialis observed was comparable to nondiabetic animals treated with extract.

**Discussion**

The increasing incidence of type 2 diabetes in men contributes to the increasing number of men with ED [1]. An increasing body of evidence supports the use of medicinal plants in the management of diabetic related complications including ED [20, 21]. In this study, the erectogenic effect of the methanolic extract from the roots of the *M. procumbens* in type 2 diabetic rats is reported.

The recorded elevated fasting blood glucose in the diabetic induced groups confirmed induction of diabetic state in the animals. While mounting behavior characterizes sexual provocation and penile orientation [1], testosterone regulates nearly every component of erectile function. In addition to increasing sexual desire, testosterone also stimulates synthesis of NO, which activates cascade of reactions leading to vasodilation in the penile tissue [22]. In the present study, the reduced mounting frequency and serum testosterone levels in the model diabetic ED rats indicated a decreased sexual desire/libido, a characteristic of ED. The observed increase in mounting frequency and testosterone levels following treatment of the diabetic rats with the extract indicated the erectogenic potential of the extract. In addition, augmented levels of testosterone and increased mounting frequency observed in the normal animals treated with extract further supported its erectogenic boosting ability.

The decreased serum levels of AChE, arginase and ACE in the extract treated groups further supported the erectogenic effect of the plant extract. Increased activities of AChE and arginase, commonly observed in diabetic state, diminishes the synthesis and bioavailability of NO, required for efficient penile erection process [23, 24]. Furthermore, the inhibitory effect of the extract on ACE activity, an enzyme that catalyzes the conversion of the angiotensin I to the active vasoconstrictor angiotensin II [25], indicates a potential to ameliorate hypertension-induced ED. Hence, the control of arginase, AChE and ACE have been reported as potential therapeutic strategy in the management or treatment of ED.

The enzymatic inhibitory activity exhibited by the extract could be attributed to the phytochemical composition of the plant, which includes saponins, tannins and alkaloids. These phytochemicals are known to inhibit the activities of arginine, AChE, ACE and PDE-5 [27-29].

The ability of the plant extract to lower the serum uric acid levels in the extract treated animals further supported its erectogenic potential. Uric acid, an end product of dietary and endogenous purine metabolism, modulate the physiological functions of various physical systems [30]. However, the link between serum uric acid level and ED is still controversial. Various reports have provided evidence that elevated uric acid level is a powerful scavenger of reactive oxygen species (ROS), thus acts as an antioxidant [31, 32]. Whereas other studies holding the opposite view have revealed that elevated level of uric acid is a potential risk factor of ED [33, 34]. In the current study we found that increased level of uric acid is associated with ED (Figure 2.C), hence, the lowered uric acid level observed on the extract treated rats could partly explain its erectogenic property.

Moreover, understanding the molecular mechanisms that underlie the development and progression of ED is also a vital objective in the management and treatment of the ailment. On one hand, PDE-5 hydrolyses cGMP, a second messenger molecule crucial for activating cascade of reactions leading to vasodilatation in the penile tissue [35]. On the other hand, RhoA kinase pathway directly suppress the expression of eNOS, which leads to diminished eNOS activity and reduced bioavailability of NO, thus inhibiting the smooth muscle relaxation and erectile process [36]. The significant downregulation of PDE-5 and RhoA along with an increased expression of eNOS observed in the extract treated group provided support and an insight into the molecular basis of the erectogenic effect of the extract. Our results are similar to those reported by Corbin [24] and Bivalacqua et al [37], who showed the ability of the crude extracts to downregulate RhoA and increase eNOS expression and thus ameliorate erectile dysfunction in diabetic induced ED. Oboh and co-workers [27] have also shown that downregulation of PDE-5 ameliorates erectile dysfunction in diabetic rats.

The ability of the extract to also lower the fasting blood glucose levels (Table 1) and serum fructosamine (Figure 2A), a substance clinically used as a marker of short-term glycemic control in diabetic patients, demonstrated its antihyperglycemic property. The elevated blood glucose levels are known to promote AGEs formation, which accumulate in the corpus cavernosal tissue, particularly in the endothelial and smooth muscle cells, and contribute to the pathogenesis of diabetic ED [38, 39]. AGEs form covalent bonds with vascular collagen, which leads to vascular thickening, reduced elasticity, endothelial dysfunction and increased vascular stiffness [7]. The obtained results from the current work thus show that the crude extract and RA-3 (our in house hyperglycemia control compound [40, 41]) partly possesses a comparable hypoglycemic effect when compared to untreated diabetic ED rats and/or Cialis treated animals, respectively.

Chronic elevated blood glucose also induces oxidative stress which underlies various complications of diabetes including endothelial dysfunction and consequent ED development. Increased activity of SOD and CAT accompanied by decreased MDA levels (a measure of lipid peroxidation) in the extract treated diabetic ED group indicated the extract’s potential to enhance antioxidant defense system. The increased protein thiol group content in the extract treated diabetic rats (Figure 2B) further indicated the ability of the extract to enhance endogenous antioxidant status. Protein thiol groups are very vulnerable to oxidation and considered as one of the most valuable body sacrificial antioxidants [42]. The antioxidant property of the extract could play a crucial role in ameliorating diabetic induced erectile dysfunction incidence. Various plants with antioxidant properties have been reported to improve erectile function in diabetic-ED rats [26, 6, 29].

Conclusions

In conclusion, the present study provides evidence that methanolic roots extract of the Maytenus procumbens ameliorates diabetic induced erectile dysfunction, suggesting that the plant could potentially be used in the management of diabetic ED. The ameliorative effects of the extract were due to an increased testosterone levels and mount frequency accompanied by inhibitory effect on arginase, ACE and AChE activities in the diabetic ED treated group. In addition, the mechanism through which the extract exerts its erectogenic potential could be attributed to its ability to downregulate PDE-5 and RhoA accompanied by upregulated eNOS. Nevertheless, the effect of the extract on smooth muscle contraction and the histopathological analysis of the penile tissue from the diabetic induced ED in rats is recommended to confirm its erectogenic potential.
